I. Objectives

Introduction

A doubly linked list is a type of linked list data structure where each node contains three components:

Data - The actual value stored in the node
Previous pointer - A reference to the previous node in the sequence
Next pointer - A reference to the next node in the sequence.

This laboratory activity aims to implement the principles and techniques in:

- Writing algorithms using Linked list
- Writing a python program that will perform the common operations in a Doubly linked list
- A doubly linked list is particularly useful when you need frequent bidirectional traversal or easy deletion of nodes from both ends of the list.

II. Methods

- Using Google Colab, type the source codes below:

```
class Node:
    """Node class for doubly linked list"""
    def __init__(self, data):
        self.data = data
        self.prev = None
        self.next = None

class DoublyLinkedList:
    """Doubly Linked List implementation"""

    def __init__(self):
        self.head = None
        self.tail = None
        self.size = 0

    def is_empty(self):
        """Check if the list is empty"""
        return self.head is None

    def get_size(self):
        """Get the size of the list"""
```

```
    return self.size

def display_forward(self):
    """Display the list from head to tail"""
    if self.is_empty():
        print("List is empty")
        return

    current = self.head
    print("Forward: ", end="")
    while current:
        print(current.data, end="")
        if current.next:
            print(" ↔ ", end="")
        current = current.next
    print()

def display_backward(self):
    """Display the list from tail to head"""
    if self.is_empty():
        print("List is empty")
        return

    current = self.tail
    print("Backward: ", end="")
    while current:
        print(current.data, end="")
        if current.prev:
            print(" ↔ ", end="")
        current = current.prev
    print()

def insert_at_beginning(self, data):
    """Insert a new node at the beginning"""
    new_node = Node(data)

    if self.is_empty():
        self.head = self.tail = new_node
```

```
        else:
            new_node.next = self.head
            self.head.prev = new_node
            self.head = new_node

        self.size += 1
        print(f"Inserted {data} at beginning")

    def insert_at_end(self, data):
        """Insert a new node at the end"""
        new_node = Node(data)

Answer the following questions:

1. What are the three main components of a Node in the doubly linked list implementation, and what does the __init__ method of the DoublyLinkedList class initialize?
2. The insert_at_beginning method successfully adds a new node to the start of the list. However, if we were to reverse the order of the two lines of code inside the else block, what specific issue would this introduce? Explain the sequence of operations that would lead to this problem:

```
def insert_at_beginning(self, data):
    new_node = Node(data)

    if self.is_empty():
        self.head = self.tail = new_node
    else:
        new_node.next = self.head
        self.head.prev = new_node
        self.head = new_node

    self.size += 1
```

3. How does the reverse method work? Trace through the reversal process step by step for a list containing [A, B, C], showing the pointer changes at each iteration

```
def reverse(self):
    if self.is_empty() or self.head == self.tail:
        return

    current = self.head
    self.tail = self.head

    while current:
        temp = current.prev
        current.prev = current.next
        current.next = temp
```

```
        current = current.prev

    if temp:
        self.head = temp.prev
```

III. Results

Answers:

1. The three main components of a node in a doubly linked list are, Data of the node, the pointer to the next node, and the pointer to the previous node. It allows traversal in both directions. The __init__ method sets up the initial state of the list by assigning head and tail as none, meaning the list is empty.

2. It will introduce a brief broken chain, because in that line of code, we are linking the new node to the head before we link the head to the new node. If we swap the places of "new_node.next = self.head" and "self.head.prev = new_node", it will do the opposite. It is going to link the old head to the new node before we tell the new node who its next to. Essentially, it is a one way only before the second line of code fixes it. Though the output will still be the same, it just temporarily breaks the link during execution.

3. The reverse method takes the list and flips the arrows of each node, so they point the opposite way. It starts at the head (A), makes A the new tail, and then goes through each node swapping its next and previous links. At the end, the last node it touched becomes the new head. So, the list [A ↔ B ↔ C] turns into [C ↔ B ↔ A].

- First iteration (A):

Current = A (prev = None, next = B).
Temp = None.
Swap arrows → A.prev becomes B, A.next becomes None.
Move current to B.

- Second iteration (B):

Current = B (prev = A, next = C).
Temp = A.
Swap arrows → B.prev becomes C, B.next becomes A.
Move current to C.

- Third iteration (C):

Current = C (prev = B, next = None).
Temp = B.
Swap arrows → C.prev becomes None, C.next becomes B.
Move current to None (loop ends).

Final

Head = C, tail = A

Forward Traversal: C ↔ B ↔ A

Backward Traversal: A ↔ B ↔ C

IV. Conclusion

In conclusion, this activity helped me understand how a doubly linked list works and how its operations affect the structure. I learned that each node has three parts which are the data, the next pointer, and the previous pointer, and these make it possible to move through the list in both directions. I also saw how the order of code in the insert function matters because switching lines can cause a short break in the links. Tracing the reverse method step by step made it clearer how the pointers change and how the head and tail are updated. Overall, this task improved my understanding of linked lists and how to work with them in programming.
